**Tang** is a C++ Template Language. It takes the form of a library which may be included in other projects. It is under active development, and you can follow its progress here:

- [YouTube playlist](#)
- [GitHub repository](#)

### 1.2 Features

The following features are planned:

- Native support for Unicode/Utf-8 strings.
- Change from template to script mode using escape tags like PHP.
- Loosely typed, with Python-like indexing and slicing of containers.
- Syntax similar to C/C++/PHP.
- Code compiles to a custom Bytecode and is executed by the Tang VM.
- Fast and thread-safe.

## 5.25 Tang::TangBase Class Reference

The base class for the Tang programming language.

```
#include <tangBase.hpp>
```

### Public Member Functions

- [TangBase](#) ()  
*The constructor.*
- [Program compileScript](#) (std::string script)  
*Compile the provided source code as a script and return a [Program](#).*

#### 5.25.1 Detailed Description

The base class for the Tang programming language.

This class is the fundamental starting point to compile and execute a Tang program. It may be considered in three parts:

1. It acts as an extendable interface through which additional "library" functions can be added to the language. It is intentionally designed that each instance of [TangBase](#) will have its own library functions.
2. It provides methods to compile scripts and templates, resulting in a [Program](#) object.
3. The [Program](#) object may then be executed, providing instance-specific context information (*i.e.*, state).

#### 5.25.2 Constructor & Destructor Documentation

##### 5.25.2.1 TangBase()

**Parameters**

<i>script</i>	The Tang script to be compiled.
---------------	---------------------------------

**Returns**

The [Program](#) object representing the compiled script.

## 5.26 Tang::TangScanner Class Reference

## Public Member Functions

- [TangScanner](#) (std::istream &arg\_yyin, std::ostream &arg\_yyout)  
*The constructor for the Scanner.*
- virtual Tang::TangParser::symbol\_type [get\\_next\\_token](#) ()  
*A pass-through function that we supply so that we can provide a Bison 3 token return type instead of the `int` that is returned by the default class configuration.*

### 5.26.1 Detailed Description

The Flex lexer class for the main Tang language.

Flex requires that our lexer class inherit from `yyFlexLexer`, an "intermediate" class whose real name is "TangTangFlexLexer". We are subclassing it so that we can override the return type of [get\\_next\\_token\(\)](#), for compatibility with Bison 3 tokens.

### 5.26.2 Constructor & Destructor Documentation

#### 5.26.2.1 TangScanner()

```
Tang::TangScanner::TangScanner (
    std::istream & arg_yyin,
    std::ostream & arg_yyout ) [inline]
```

The constructor for the Scanner.

The design of the Flex lexer is to tokenize the contents of an input stream, and to write any error messages to an output stream. In our implementation, however, errors are returned differently, so the output stream is never used. It's presence is retained, however, in case it is needed in the future.

For now, the general approach should be to supply the input as a string stream, and to use `std::cout` as the output.

#### Parameters

<i>arg_yyin</i>	The input stream to be tokenized
<i>arg_yyout</i>	The output stream (not currently used)

### 5.26.3 Member Function Documentation

#### 5.26.3.1 get\_next\_token()

```
virtual Tang::TangParser::symbol_type Tang::TangScanner::get_next_token ( ) [virtual]
```

A pass-through function that we supply so that we can provide a Bison 3 token return type instead of the `int` that is returned by the default class configuration.

**Returns**

A Bison 3 token representing the lexeme that was recognized.
